

THE PROBLEM

When you're treating a complex, heavily pretreated patient, you need to know what the current evidence says for that exact clinical picture, and you need to know it again every time the patient's status changes. That's harder than it should be. The evidence that actually matters is usually spread across a paper's eligibility criteria, methods, and results, not sitting in one clean summary. A real patient has biomarkers, prior treatment, and other factors that a simple keyword search flattens into noise. And the way a chart describes a patient ("no longer a surgical candidate") often doesn't match the language a paper uses ("unresectable"), so relevant studies get missed even when they're exactly on point. With hundreds of new oncology papers published every week, keeping up by hand isn't realistic on top of a full clinic load.

WHAT PAXIS DOES

Paxis reads oncology literature the way you would if you had unlimited time: understanding what each study is actually about, not just matching keywords. Describe a patient in plain language or enter a structured profile, and you get back the studies that genuinely match that case, with the relevant evidence already pulled out, not just a list of titles to dig through yourself. It doesn't stop after one search either. Once a patient is on record, their diagnosis, biomarkers, and treatment response stay attached to that case, so you can keep asking questions as things change. Paxis also keeps watching new literature in the background and tells you the moment something new matches, so you're not the one who has to remember to check again.

WHAT IT DOES THAT OTHERS CAN'T

Remembers the patient, not just the question

Diagnosis, biomarkers, and treatment response all stay attached to the case. Ask what's working, what isn't, and why, and Paxis answers based on that specific patient, not a generic search.

Looks at the whole patient, not one detail

Every part of the case, diagnosis, biomarkers, treatment history, and more, gets considered together, instead of one flattened search that loses the details that actually matter.

Never stops watching

Turn on alerts for a saved patient and Paxis keeps checking new literature in the background, letting you know the moment a matching study is published. No manual re-checking, ever.

Filters before it shows you anything

Every result is checked against the full patient picture before you ever see it, so you're not sorting through matches that only look relevant on the surface.

Understands how you actually chart

Paxis automatically translates the way you describe a patient into the terms the literature actually uses, so a match doesn't get missed just because the wording is different.

Covers the whole workflow, not just search

Intake, ongoing questions, matching, treatment comparison, and trial finding, all in one place built around your patient, not a search box.

BUILT AND RUNNING

- **A live product you can use today**, not a prototype or a pitch deck
- **A real oncology literature library** already loaded in and ready to search
- **Patient records that stay with the case**, tracking treatment response over time
- **Standing alerts already running**, watching new literature so you don't have to
- **Matching that checks the whole patient**, not just keywords, before showing you a result
- **A complete clinical workflow**: intake, matching, treatment comparison, trial finder, and analytics
